

Lab 1

Step 1: Do the preliminary tasks

Step 2: Do the Lab tasks.

A. Preliminary Tasks:

A1) Read Notes: IntroToLinux.txt. Try each command. You should know the following commands very well:

pwd = path to current directory

ls = list files in current directory (ls -a and ls -l options)

cd = change directory

mkdir = make a new directory

rm = delete a file

cp = copy a file from a source folder to a destination folder

mv = move a file from a source folder to a destination folder

And the meaning of the following symbols/words:

home directory = your account's main folder. Each account has a folder in the home/ directory where all your files will be saved and you have permissions to create, write and execute files

~ = path to your home directory

.. = one directory down

=====

A2) Create a directory called CSC16 on your home directory.

~/CSC16

=====

A3) Go to CSC16 folder. Create a directory Lab1.

=====

A4) Follow the steps in Notes1_about_gnu_compiler.txt Gnu gcc compiler is the most used C++ compiler. It is used by many IDEs.

You should know how to compile a c++ file using the g++ command.

You should know how to run or execute a c++ file: ./fileName.exe

=====

A5) Read CPPprogramStructure.cpp

You should know the structure of a C++ program.

What is the role and place of #include directives.

What is the role of main function.

What does cout and cin.

=====

A6) Follow the steps in EclipseNotes. Eclipse CDT is a widely used IDE for C++. You can install it on your own computers. We will use Eclipse to compile and run C++ programs. Eclipse uses gcc compiler to compile C++ programs.

LAB 1.1 – TRY IT: Compiling and Running Your First Program

Step 1: Copy `greetings.cpp` in your CSC16/Lab1 folder. Open it in a text editor. Copy and past the code in Eclipse (`greetings.cpp`)

```
1 // greetings.cpp
2 // This program prints a message to greet the user.
3 #include <iostream>           // Needed to do C++ I/O
4 #include <string>             // Needed by some compilers to use strings
5 using namespace std;
6
7 int main ()
8 {
9     string name;              // This declares a variable to
10                               // hold the user's name
11     // Get the user's name
12     cout << "Please enter your first name: ";
13     cin  >> name;
14
15     // Print the greeting
16     cout << "Hello, " << name << "." << endl;
17
18     return 0;
19 }
```

Step 2: Read the source code. What do you think the program will display when it is run if the user enters the name Adam on line 12? _____

Step 3: Compile the program. You should see a message at the bottom of the screen telling you the program has compiled correctly. This message will be different for each compiler, but may look something like this:

```
greetings.o - 0 error(s), 0 warning(s)
```

Notice what the message looks like on *your* system.

Step 4: Execute the program. Enter the name Adam when the program prompts you for a name. Did you get the output you expected? _____ Run the program again, and this time enter *your* first name when you are prompted for a name. Write a copy of the output here.

Computer Program Errors

The `greetings.cpp` program compiled and ran correctly because it contained no errors. However, there are three different types of errors that can occur in a computer program, and all of these need to be found and fixed before a program will work correctly. Each of these three errors is examined below.

LAB 1.2 – Syntax Errors

A *syntax error* in a program, just like a syntax error in English, means that a grammar rule has been broken. One or more of the programming statements in the source code do not follow the rules for how a C++ program must be written. Let's take a look at the most commonly made C++ syntax error, an omitted semi-colon.

Step 1: Remove the semi-colon on line 12 of the `greetings.cpp` program. To do this you can simply place your cursor at the end of line 12 and press the back space key. Once the semi-colon is gone, recompile the program and look at the error message displayed at the bottom of the screen. The exact message you get will depend on which compiler you are using, but it will likely look something like this:

```
greetings.cpp:13: error: expected ';' before "cin"
```

Always read the message carefully. Sometimes it is clear what is wrong. Other times the message may be confusing to a new programmer, but you will get better at deciphering compiler error messages as you gain more experience. This message is quite clear. It says that a semi-colon is missing before the word `cin`.

Notice that the compiler error message also includes a line number indicating the approximate, but not exact, location where the error occurred. In this case the error occurred at the end of line 12, but the compiler message reports the error as occurring on line 13. This is because the compiler did not detect the problem until it reached the `cin` on line 13. Any time you get a compiler error message and do not see a problem in the line reported, try checking the previous line.

Step 2: A program containing compiler errors cannot be run until the errors are fixed and the program is recompiled. Put the semi-colon back in at the end of line 12 and then compile the program again. If you have done it correctly, it will compile with no errors this time. Now you can run the program again.

LAB 1.3 – Run-time Errors

A *run-time error* occurs when a program instruction tells the program to do something it is unable to correctly do. This type of error cannot be detected by a compiler because no syntax rules have been broken. So the program will compile but, as the name suggests, something will go wrong when the program is run. In some cases a run-time error causes the program to abort; in others it continues running, but produces incorrect results. Let's take a look at a common run-time error, attempting to divide by zero.

Step 1: Add the `average.cpp` program from your `Lab1` folder to the project. Here is a copy of the source code.

```
1 // average.cpp
2 // This program finds the average of two numbers.
3 // It contains two errors that must be fixed.
4 #include <iostream>
5 using namespace std;
6
7 int main ()
8 {
9     int size = 0;                // The number of values to be averaged
10    double num1,
11           num2,
12           average;              // Average of num1 and num2
13
14    // Get the two numbers
15    cout << "Enter two numbers separated by one or more spaces: ";
16    cin  >> num1 >> num2;
17
18    // Calculate the average
19    average = num1 + num2 / size;
20
21    // Display the average
22    cout << "The average of the two numbers is: " << average << endl;
23
24    return 0;
25 }
```

Step 2: Read through the source code to see if you can spot any errors in the program. Two lines contain errors, but even if you can find them, do not fix them yet.

Step 3: Compile the program. Since it contains no syntax errors, the compiler should not detect any errors.

Step 4: Run the program and, at the prompt, enter `10 5`. Did the run-time error cause the program to abort or to produce incorrect results? If it ran without aborting it probably displayed something like this:

```
Enter two numbers separated by one or more spaces: 10 5
The average of the two numbers is: 1.#INF
```

Step 5: The error occurs on line 19 when a quantity is divided by `size`. Notice that `size` is set in line 9 to 0. Correct the error by changing line 9 of the source code to set `size` equal to 2 so that the quantity on line 19 will be divided by 2. Then recompile and rerun the program, again entering 10 and 5 for the two numbers. The output should now look like this:

```
Enter two numbers separated by one or more spaces: 10 5
The average of the two numbers is: 12.5
```

LAB 1.4 – Logic Errors

A *logic error* causes a program to work incorrectly. It doesn't break any syntax rules and doesn't tell the computer to do anything it is unable to do. Instead it occurs when the program logic is wrong because what the programmer tells the program to do does not match what he or she means for it to do. If you were explaining to someone how to do laundry, it would be a logic error to tell them to put the laundry in the oven, when what you meant was for them to put it in the washer. Another logic error would occur if you told them to wash the laundry and then fold it, but forgot to tell them to dry it. It would also be a logic error if you got the steps out of order and told them to first fold the laundry, then dry it, and then finally to wash it. Likewise, for a program to be correct each instruction must be correct, no instructions must be omitted, and the instructions must be carried out in the right order.

Let's look at a logic error that causes a program to carry out two mathematical operations in the wrong order.

Step 1: Look again at the output created by the `average.cpp` program in Step 5 of Lab 1.3 above. Notice that the user entered 10 and 5, but the program reported the average to be 12.5, rather than 7.5. The error occurs on line 19. To find an average of a set of values, you must add the values *before* you divide by the number of values. But the code on line 19 tells the computer to divide the value stored in `num2` by `size` before adding the result to the value stored in `num1`. You will learn more in chapters 2 and 3 about how to write correct mathematical statements in C++. For now, just add parentheses on line 19 so it says:

```
average = (num1 + num2) / size;
```

Step 2: Recompile and rerun the program, again entering 10 and 5 at the prompt. Now that you have corrected the logic error, you should get the following correct result.

```
Enter two numbers separated by one or more spaces: 10 5
The average of the two numbers is: 7.5
```

LAB 1.5 – Fix the Errors

Step 1: Remove `average.cpp` from the project and add `findErrors.cpp` to the project. Here is a copy of the source code.

```
1 // findErrors.cpp
2 // This program has one syntax error and one logic error. Find and fix them.
3 // PUT YOUR NAME HERE.
4 #include <iostream>
5 using namespace std
6
7 int main ()
8 {
9     double length = 0,           // Length of a room in feet
10         width = 0,              // Width of a room in feet
11         area;                   // Area of the room in sq. ft.
12
13     // Get the room dimensions
14     cout << "Enter room length (in feet): ";
15     cin  >> length;
16
17     cout << "Enter room width (in feet): ";
18     cin  >> length;
19
20     // Compute and display the area
21     area = length * width;
22     cout << "The area of the room is " << area << " square feet." << endl;
23
24     return 0;
25 }
```

Step 2: Put your name on line 3. Then compile the program. It contains one syntax error and one logic error.

Step 3: Use the compiler error message to help you locate the syntax error and fix it.

Step 4: Once the program compiles with no errors, run the program, and examine the output. Analyze what is going wrong so you can find and fix the logic error in the program. Once you have it running correctly the output should look like the following:

```
Enter room length (in feet): 15
Enter room width (in feet): 10
The area of the room is 150 square feet.
```
